Science (Bio)

- Stentor - a genus of single celled Eukaryotes.
 - large (up to 4 mm long.)
- Biggest tardigrade up to 1.5mm.
- Stentors are denser than water. - can stretch a lot too. Also able to anchor.
- Stentor Coeruleus can be as big as a grain of rice.
 - ↑
 - part of a group called ciliates, and have a mouth.
 - Stentor Coeruleus can regenerate, and feel stimuli.
 - Macronucleus and cell membrane are needed if a stentor can regenerate.
- Genes are the instructions for particular traits.
- Genome are all of your genes
- Poly ploid - even a fraction can rebuild itself.
- Whole regen process takes about 48 hours to complete.
- Stentor hates the light. They are blue because of a chemical within them.
- Rotifer - multi cellular creature. (found in muddy water)
- A type of Invertebrate (no backbone)
- The Rotifers phylum, we have one sample of from 1.5 million years ago, and they haven't changed much since.
- 100-500 microns long (1mm)
- 1 mm = 0.001 meters, 1 μm = 0.000,001 meters.
- Rotifers translates to wheel borer.
- Rotifers has jaws. • Parthenogenesis (Reproduction) nervous system.
- About 25% of the cells in its system are for its nervous system.
- Then makes a... (incomplete)
